The cultural diversity of culinary practice, as illustrated by the variety of regional cuisines, raises the question of whether there are any general patterns that determine the ingredient combinations used in food today or principles that transcend individual tastes and recipes. We introduce a flavor network that captures the flavor compounds shared by culinary ingredients. Western cuisines show a tendency to use ingredient pairs that share

Network analysis and data mining in food science: the emergence of computational gastronomy

Sebastian E Ahnert

Abstract

The rapidly growing body of publicly available data on food chemistry and food usage can be analysed using data mining and network analysis methods. Here we discuss how these approaches can yield new insights both into the sensory perception of food and the anthropology of culinary practice. We also show that this development is part of a larger trend. Over the past two decades large-scale data analysis has revolutionized the biological sciences, which have experienced an explosion of experimental data as a result of the advent of high-throughput technology. Large datasets are also changing research methodologies in the social sciences due to the data generated by mobile communication technology and online social networks. Even the arts and humanities are seeing the establishment of 'digital humanities' research centres in order to cope with the increasing digitization of literary and historical sources. We argue that food science is likely to be one of the next beneficiaries of large-scale data analysis, perhaps resulting in fields such as 'computational gastronomy'.

Food-Bridging: A New Network Construction to Unveil the Principles of Cooking

Tiago Simas^{1,2*}, Michal Ficek¹, Albert Diaz-Guilera^{3,4}, Pere Obrador¹ and Pablo R. Rodriguez¹

¹ Telefonica Research, Edificio Telefonica, Barcelona, Spain, ² Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, ³ Departament de Fisica de la Materia Condensada, Universitat de Barcelona, Barcelona, Spain,

In this manuscript, we propose, analyze, and discuss a possible new principle behind traditional cuisine: the Food-bridging hypothesis and its comparison with the food-pairing hypothesis using the same dataset and graphical models employed in the food-pairing study by Ahn et al. (2011). The Food-bridging hypothesis assumes that if two ingredients do not share a strong molecular or empirical affinity, they may become affine through a chain of pairwise affinities. That is, in a graphical model as employed by Ahn et al., a chain represents a path that joints the two ingredients, the shortest path represents the strongest pairwise chain of affinities between the two ingredients. Food-pairing and

Caramelized sugar

Category: [Caramel](#)

Sugar is the generalized name for sweet, short-chain, soluble carbohydrates, many of which are used in food. They are carbohydrates, composed of carbon, hydrogen, and oxygen. There are various types of sugar derived from different sources. Simple sugars are called monosaccharides and include glucose (also known as dextrose), fructose and galactose. The table or granulated sugar most customarily used as food is sucrose, a disaccharide. (In the body, sucrose hydrolyses into fructose and glucose.) Other disaccharides include maltose and lactose. Longer chains of sugars are called oligosaccharides. Chemically-different substances may also have a sweet taste, but are not classified as sugars. Some are used as lower-calorie food substitutes for sugar described as artificial sweeteners. (from [Wikipedia](#))

Nutrition: [Peanut-Free](#), [Lupin-Free](#), [Celery-Free](#)

Dark caramel

Category: [Caramel](#)

Caramel (/kærəməl/ or /karməl/) is a beige to dark-brown confectionery product made by heating a variety of sugars. It can be used as a flavoring in puddings and desserts, as a filling in bonbons, or as a topping for ice cream and custard. (from [Wikipedia](#))

Nutrition: [Peanut-Free](#), [Lupin-Free](#), [Celery-Free](#)

©iStock-stray_cat

Quan es posa al foc, el sucre, sol o amb una mica d'aigua, canvia ràpidament de temperatura i experimenta diferents transformacions. Cada fase o estadi de coccció es defineix per un interval de temperatura i per una viscositat i té utilitats concretes en cuina i pastisseria.

Les diferents fases de cocció del sucre es poden comprovar de diverses maneres. La manera més precisa d'elaborar **xarop** al punt de cocció que es necessita és mesurant-ne la densitat (en **graus Brix**) i la temperatura (en graus centígrads). Tanmateix, hi ha una manera tradicional de detectar les fases de cocció del sucre sense aparells de mesura ni escales de cap mena, i de manera igualment precisa. Això és mitjançant el tacte amb els dits polze i índex, i amb estris de cuina tan senzills com una cullera o una escumadora, a partir d'unes característiques físiques particulars basades en la viscositat del xarop, és a dir, la resistència que ofereix el fluid al moviment relatiu de les seves partícules. I una bona vista.

Per mirar de fixar i acordar les denominacions catalanes adequades per a cada fase i delimitar els conceptes, sobretot pel que fa a l'interval de temperatura a què correspon cadascuna, vam reunir al TERMCAT uns quants especialistes de l'àmbit de la pastisseria, vinculats a la **UB-Bullipèdia**. Els resultats d'aquesta reunió, amb aportacions també d'altres especialistes, van ser estudiats i ratificats posteriorment pel Consell Supervisor.

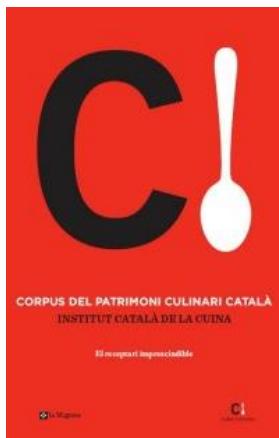

Els diferents punts de cocció d'un xarop tenen uns noms tan descriptius i suggeridors com **punt de fil**, **punt volant**, **punt de bola** o **punt de caramel**. Per exemple, se submergeixen els dits polze i índex en aigua freda i tot seguit s'agafa una mica de xarop, se separen els dits i el xarop agafa la forma de fil, fins que es trenca (**punt de fil**). El fil pot trencar-se de seguida (**fil fluix**) o pot arribar a ser una mica més llarg i trigar una mica més a trencar-se (**fil fort**). O bé s'agafa xarop amb una escumadora i se'l fa passar, bufant, a través dels forats i el xarop forma bombolles (**punt volant**). Es pot agafar també amb una cullera, submergir-la un moment en un recipient amb aigua freda, i llavors agafar el xarop amb els dits i formar una bola (**punt de bola**) que es pot aixafar més fàcilment o no tant. O quan, a mesura que es va escalfant, el xarop va agafant color, ens hem de fixar en tota la gamma de grocs, ocres i marrons per determinar quin **punt de caramel** tenim. Fins que el xarop forma escuma a la superfície, aleshores tenim **sucre cremat**, que ja no és dolç, encara que es digui sucre, i és l'últim sospir abans de la carbonització.

Tot aquest món de termes al voltant de la cocció del sucre el podeu trobar en forma de fitxes terminològiques a la **Neoloteca** i al **Cercaterm**.

Mel d'oli

La **mel d'oli** és una elaboració d'oli d'oliva texturitzat, viscosa, dolça i groguenca, feta amb [aigua](#), [oli d'oliva](#) i agents texturitzants ([isomalt](#) i [sucre](#)), que li confereixen una textura untuosa semblant a la [mel](#).^{[1][2][3]}

Composició i procés d'elaboració

[modifica](#) [modifica el codi](#)

Aquesta elaboració consisteix en una dissolució de sucres ([isomalt](#), [sucre en pols](#) i [glucosa](#)) en aigua. En dissoldre's en aigua (medi líquid), els sucres (sòlids) formen enllaços temporals, però forts, ja que les partícules sòlides són atretes per les líquides, que trenquen la seva estructura rígida. Així les partícules disagregades del sòlid es van situant en els espais buits que hi ha entre les partícules de líquid i formen la dissolució. Mentre que l'oli no té gaire poder de dissolució de sucres i no s'arribarien a dissoldre i integrar correctament.^[cal citació]

Durant la primera fase d'elaboració de la recepta, l'aigua, a més de la seva afinitat per dissoldre sucres, es fa servir per poder aplicar calor als sucres i evitar que es caramel·litzin. L'elaboració del xarop a una temperatura de 90 °C permet augmentar la solubilitat de l'aigua. A més, els xarops a baixa temperatura es formen cristalls petits i fins.^[cal citació]

Per fer aquesta elaboració s'utilitzen tres tipus de sucre.^[cal citació]

- **Sucre Ilustre:** sacarosa amb un poder edulcorant del 100 %, ja que és el sucre de referència per als graus de dolçor. S'utilitza sobretot per aportar dolçor a l'elaboració, i perquè és fàcil de dissoldre en aigua, ja que és el segon sucre més soluble en aquest medi.
- **Glucosa en pols:** sucre amb una capacitat edulcorant del 75 %. S'usa per a la capacitat que té de prevenir la cristal·lització dels sucres i d'aportar elasticitat a les masses. A més, retarda la dessecació dels productes i és un anticristal·litzant de gelats (elaboracions amb un alt contingut

Terminology from the Past to the Future

April 25, 2017 11:59 am

A box of cards

At a very young age I had the good luck and privilege of joining the **translation service** of an **international organisation**. I was fascinated by the **multilingual environment** which allowed me to use and practice all the languages I had studied, and also by the extremely interesting texts I had to translate in the European Parliament – for instance, the first Treaty of the European Union, high quality political speeches, reports in every field of the European legislation. It was easy to fall in love with my job, to fall in love with every single text that I was creating as my own new original in the target language. To always try to find the exact equivalent of the initial idea of the author, of the concept, and to transmit it to my reader with the **best terms** available. Because translating is a permanent exercise in **terminology**, and producing **quality translation** depends on the success of this exercise.

Terminology [...] provides the methodology for analysing and organising the semantic web, structuring big data, and streamlining philosophical thinking through the ontologies that connect related concepts. Thus we can say that terminology studies provide a new way of thinking and dealing with the semantic web.
